

⇒ reduce()

It works by calling function we passed for the first two items in the sequence. The result returned by the function is used in another call to function alongside with the next element. This process repeats until we have gone through all the elements in the sequence.

Syntax:

`reduce(function, sequence[, initial])`

⇒ zip()

This function is used to combine two or more lists into a single iterable, where elements from corresponding positions are paired together.

The resulting iterable contains tuples, where first element from each list is paired together, and second element from each list is paired together, and so on.

Syntax:

`zip(*iterables)`

⇒ id()

The `id()` function returns a unique id for the specified object. All objects in python has its own unique id. The id is assigned to the object when it is created.

Syntax:-

`id(object)`

⇒ enumerate()

This function adds a counter to an iterable and returns the enumerable object as the output.

Syntax:-

`enumerate(iterable, start=0)`

⇒ map()

The `map()` function iterates through all items in the given iterable and executes the function we passed as an argument on each of them.

Syntax:-

`map(function, iterable(s))`

⇒ filter()

It is similar to map(), it takes a function object and an iterable and creates a new list.

filter() forms a new list that contains only elements that satisfy a certain condition

Syntax:

filter(function, iterable(s))

⇒ map()

Syntax:

as per output.

Iterable and returns the iterable object

This function adds a counter to an

enumerate()

(object)

Syntax:

enumerate.

It is assigned to the object when it is

by default it starts with 0 and

it starts with 1/A counter for
